**DESCRIPTION**

The PL123-05/-09 (-05H/-09H for High Drive) are high performance, low skew, low jitter zero delay buffers designed to distribute high speed clocks. They have one (*PL123-05*) or two (*PL123-09*) low-skew output banks, of 4 outputs each, that are synchronized with the input. The *PL123-09* allows control of the banks of outputs by using the S1 and S2 inputs as shown in the Selector Definition table on page 2.

The synchronization is established via CLKOUT feed back to the input of the PLL. Since the skew between the input and output is less than  $\pm 100\text{ps}$ , the device acts as a zero delay buffer. The input output propagation delay can be advanced or delayed by adjusting the load on the CLKOUT pin.

These parts are not intended for 5V input-tolerant applications.

### INPUT / OUTPUT SKEW CONTROL

The PL123-05/-09 will achieve Zero Delay from input to output when all the outputs are loaded equally. Adjustments to the input/output delay can be made by adding additional loading to the CLKOUT pin. Please contact PhaseLink for more information.

**LAYOUT RECOMMENDATIONS**

The following guidelines are to assist you with a performance optimized PCB design:

**Signal Integrity and Termination Considerations**

- Keep traces short!
- Trace = Inductor. With a capacitive load this equals ringing!
- Long trace = Transmission Line. Without proper termination this will cause reflections ( looks like ringing ).
- Design long traces as “striplines” or “microstrips” with defined impedance.
- Match trace at one side to avoid reflections bouncing back and forth.

**Decoupling and Power Supply Considerations**

- Place decoupling capacitors as close as possible to the VDD pin(s) to limit noise from the power supply
- Addition of a ferrite bead in series with VDD can help prevent noise from other board sources
- Value of decoupling capacitor is frequency dependant. Typical values to use are 0.1 $\mu$ F for designs using frequencies < 50MHz and 0.01 $\mu$ F for designs using frequencies > 50MHz.

**Typical CMOS termination**

Place Series Resistor as close as possible to CMOS output

Connect a 33  $\Omega$  series resistor at each of the output clocks to enhance the stability of the output signal
